Brief (1 slide) Introduction to Supervised Learning

Supervised Learning

Construction of the Dataset

TNG100 Cosmological Hydrodynamical Simulation

(<https://www.tng-project.org/>)

- Planck cosmology
- 106.5 Mpc by side
- 1820^3 DM particles
- 1820^3 hydrodynamic cells
- DM resolution $7.5 \cdot 10^6 M_\odot$
- Baryon resolution $1.4 \cdot 10^6 M_\odot$
- 136 snapshots from $z=127$ to $z=0$

| Property | Criterium |
|---------------------|---|
| Simulation snapshot | 99 ($z = 0$) |
| Stellar mass | $10^{10} M_\odot \leq M_\star \leq 10^{12} M_\odot$ |
| Star formation rate | $\text{SFR} \geq 0.1 M_\odot/\text{yr}$ |
| Central galaxy | SubhaloParent = 0 |
| Cosmological origin | SubhaloFlag = 1 |

TNG100 ($z = 0$)

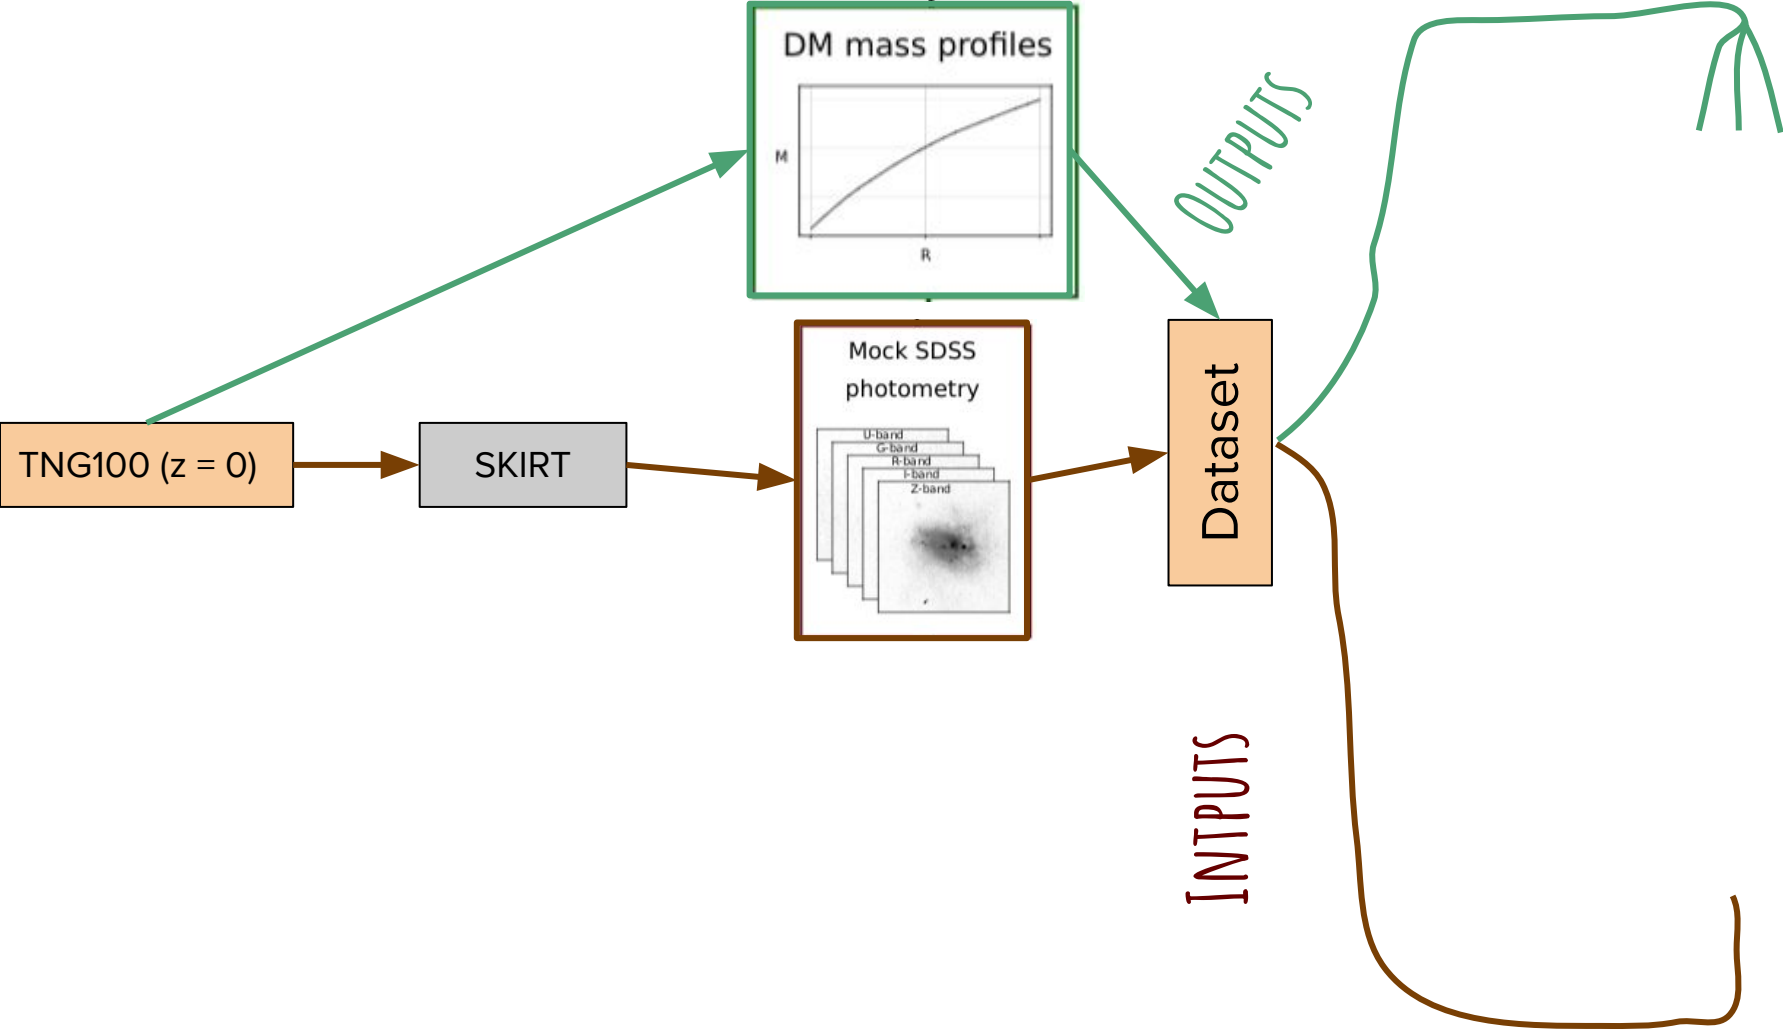

Radiative transfer code which emulates the stellar emissions and subsequent light-ray propagation to the observer, taking into account the absorption and re-emission by dust.

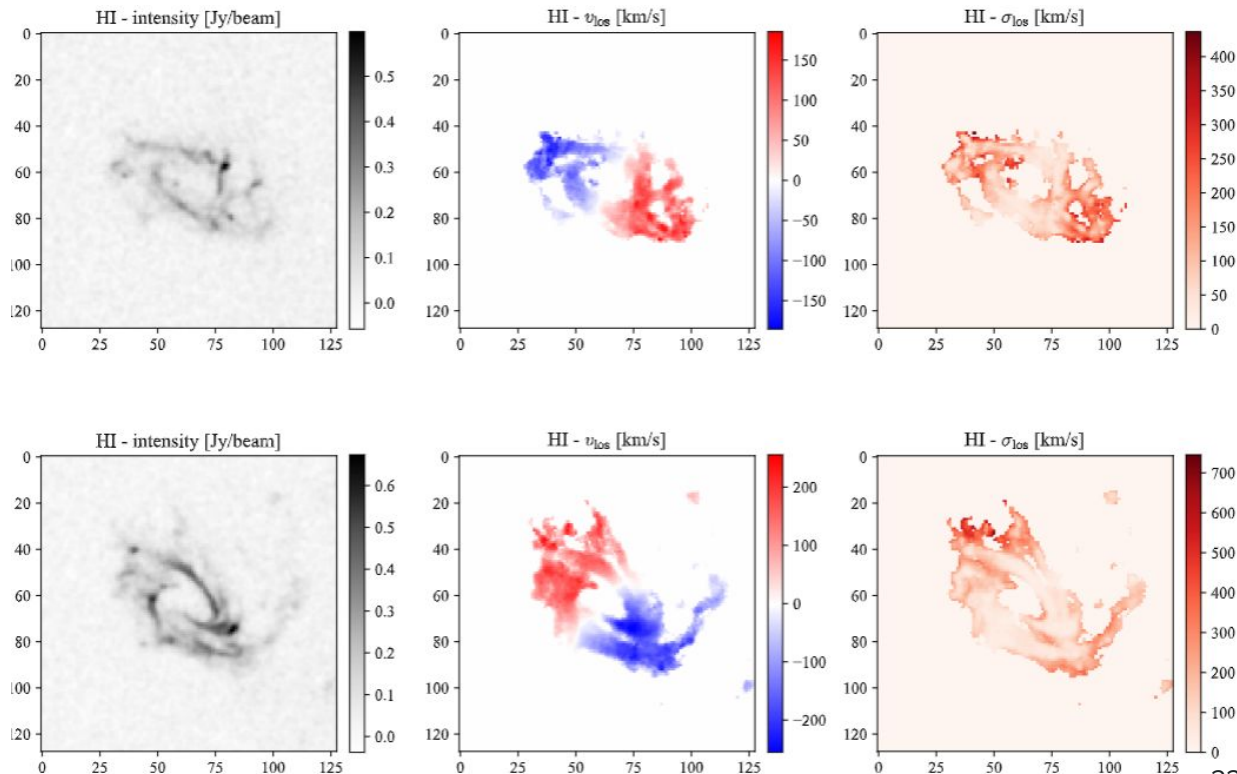

SED interpolated from template family for each particle or cell

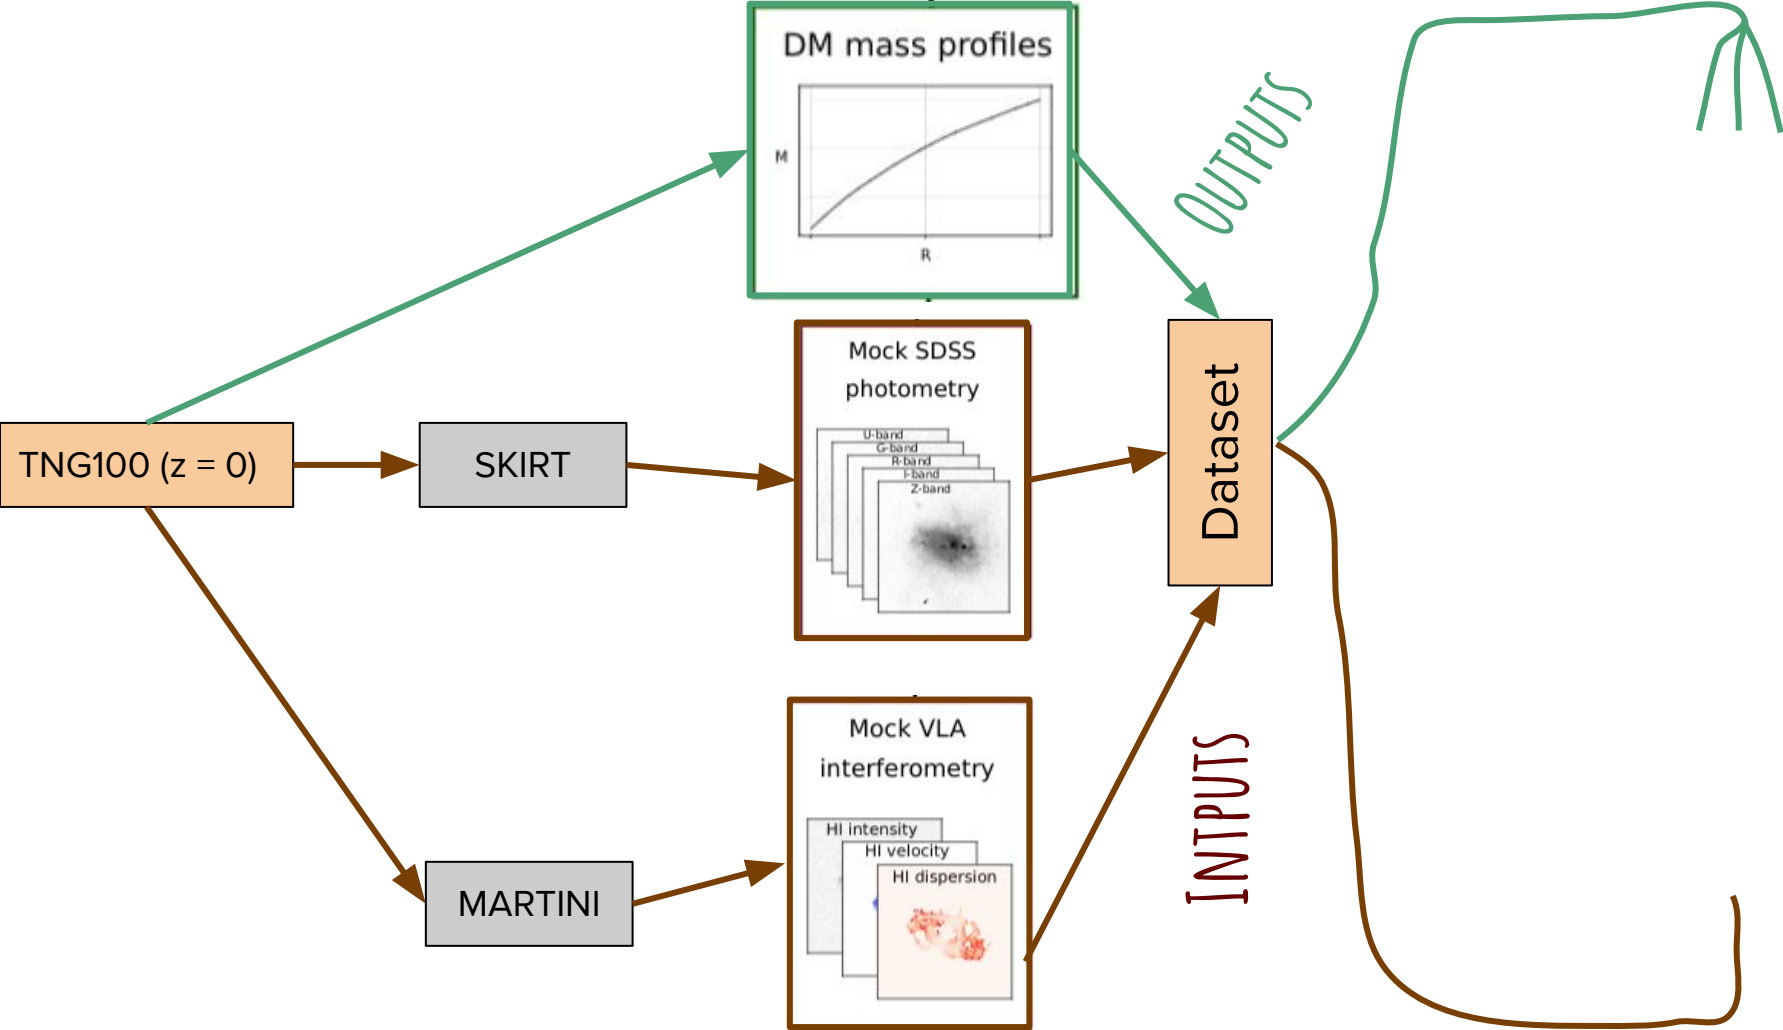

MARTINI ([1706.07478](https://doi.org/10.1002/1467-9796(200607)1706.07478) ; <https://github.com/kyleaoman/martini>)

Allows for the creation of synthetic resolved HI line observations (i.e. data cubes) directly from the snapshot of a hydrodynamic simulation, and its posterior analysis.

Convolutional layers

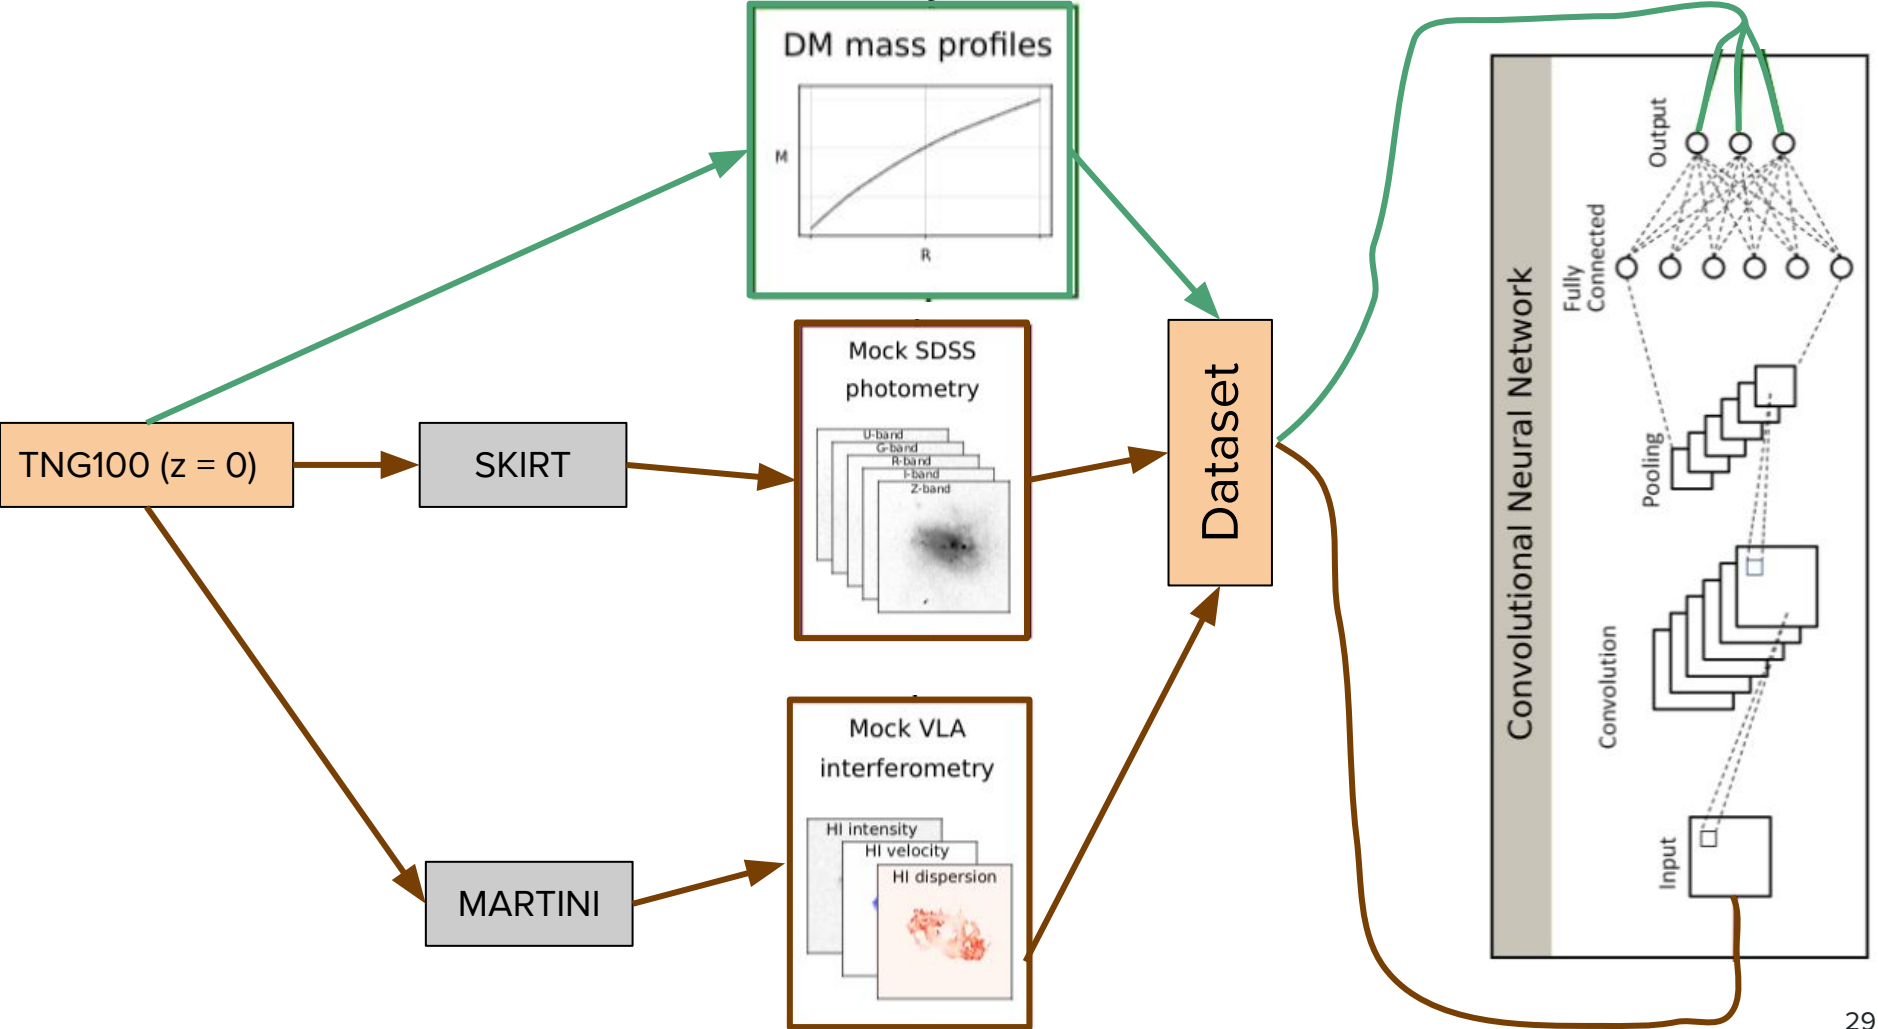

Pooling layers

Dropout

| Layer | Details |
|---------------------|--|
| 2D convolution | 64 kernels, 5×5 px kernel size, 2 px stride, ReLU activation 2 px pooling 50% dropout fraction |
| 2D max pooling | |
| Dropout | |
| Batch normalization | |
| 2D convolution | 128 kernels, 5×5 px kernel size, 2 px stride, ReLU activation 2 px pooling 50% dropout fraction |
| 2D max pooling | |
| Dropout | |
| Batch normalization | |
| 2D convolution | 256 kernels, 5×5 px kernel size, 2 px stride, ReLU activation |
| Batch normalization | |
| Dense | 256 units, ReLU activation 50% dropout fraction |
| Dropout | |
| Batch normalization | |
| Dense | 128 units, ReLU activation 50% dropout fraction |
| Dropout | |
| Batch normalization | |
| Dense | 64 units, ReLU activation 50% dropout fraction |
| Dropout | |
| Batch normalization | |
| Dense (output) | 20 units, linear activation |

Results

Comparison between different architectures

$$\Delta_{\text{MSE}}(R_i) = \left[\frac{1}{N} \sum_{j=1}^N \left(\frac{\mu_j(R_i) - \hat{\mu}_j(R_i)}{\hat{\mu}_j(R_i)} \right)^2 \right]^{1/2}$$

- Architecture A
- Architecture B
- Architecture C
- ResNet50

Comparison between different inputs

Prediction of the dark matter profile

Galaxy ID: 108013

Galaxy ID: 60744

Understanding the results

$$S_{ij} \equiv \frac{\partial y}{\partial x_{ij}}$$

R = 6 kpc

Understanding the results

$R = 48 \text{ kpc}$

Comparison with RC analysis

Conclusion and Future Work

- Our algorithm is able to reconstruct the DM distribution profile with high performance throughout the extension of the galaxy.
- The highest performance is achieved in the intermediate regions with a mean square error below 0.2 using all the photometric and spectroscopic information.
- Even in the absence of spectroscopic information, our method is able to recover the dark matter profile with a mean square error below 0.3 in the intermediate regions.
- Our reconstruction of the DM distribution is completely data-driven, and does not need any assumption on the shape nor the functional form of the DM profile.
- The method developed here is applicable to different types of galaxies since it does not rely on explicit physical assumptions regarding the dynamical state of the system.
- The results achieved have been obtained for galaxies with masses in the range $\sim 10^{10}$ - 10^{12} M_{\odot} but the methodology can be extended to a broader mass range.

- We will make a comparison with the dark matter profile obtained through the traditional rotation curve analysis for the simulated galaxies.
- Study the robustness of our results to the hydrodynamical cosmological simulation.
- Apply our method to real galaxies and compare the results with other estimations.

THANK YOU
